Finding satisfying assignments

Let ϕ be a formula with n boolean variables x_1, x_2, \dots, x_n . We are given a polynomial time algorithm SAT that can decide satisfiabilty of a formula, i.e., $SAT(\phi)$ returns true or false depending on whether or not the formula ϕ is satisfiable. We can use the following logic to find a satisfying assignment in polynomial time, by using the algorithm SAT.

Algorithm SATASSIGN(\$): Find the satisfying assigments (SATLVAL[1...n]) for the n-variable boolean formula ϕ if SAT(φ)=false then

return null (not satisfiable)

3: end if

4: SATVAL[1...n] + (false, false, ..., false)

5: for i = 1 to n do

if $SAT(\phi \wedge x_i)$ =true then

 $\phi \leftarrow SUBSTITUTE(\phi, x_i, true)$ (traverse ϕ and substitute x_i with true in all the clauses)

 $STATVAL[i] \leftarrow true$ 8:

95 else if $SAT(\phi \wedge x_i)$ =false then

 $\phi \leftarrow SUBSTITUTE(\phi, x_i, false)$ {traverse ϕ and substitute x_i with 10: false in all the clauses)

 $STATVAL[i] \leftarrow false$

end if 12:

13: end for

14: return SATVAL

You didn't need to write out an algorithm, but since you did, pay attention to what you write!

9

Analysis

- If the forumula is not satisfiable, line 1 3 of the algorithm executes which
 just invokes ploynomial time algorithm SAT and returns null, taking polynomial time only.
- If the formula is satisfiable, the for loop 5 13 executes for n times and in
 ith iteration it assigns all the x_is in φ either true or false, which is again
 polynomial time (precisely, if φ has m clauses and each clause has at most
 one instance of a variable, this takes at most O(m) time).
- Hence the overall algorithm for SATASSIGN is a ploynomial time algorithm.

$2CNF - SAT \in P$

2 - CNF can be represented in the following form:

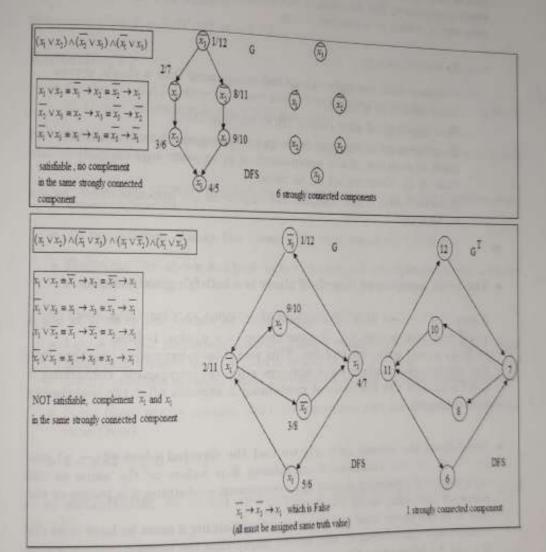

$$-F = \bigwedge_{i=1,...m} C_i$$

- Each clause C_i is a 2-literal caluse and hence of the form
 (y ∨ z) ≡ (y → z) ≡ (z → y).
- $-y, z \equiv x_i$ or $\bar{x_i}$, with $i, j \in 1 ...n$.
- F contains total m clauses formed using total n literals.
- If there is a one literal clause, it must be assigned to true, trivially.
- Construct a directed graph G(V, E), with
 - $-v_i$ ∈ V corresponding to the literal x_i , $\forall i = 1 ... n$.
 - $\theta_i \in V$ corresponding to the negated literal $\bar{x_i}, \ \forall i=1\dots n$
 - -|V| = 2n
 - $-(v_i, v_j) \in E \Leftrightarrow x_i \rightarrow x_j \in F$.
 - -e.g., $C_k = \vec{x}_i \lor x_j \equiv x_i \rightarrow x_j \equiv \vec{x}_j \rightarrow \vec{x}_i \in F \Leftrightarrow (v_i, v_j), (\vec{v}_j, \vec{v}_i) \in E.$
- The 2-CNF formula F is satisfiable iff no pair of complimentary literals
 are in the same strongly connected component of G. This is illustrated in
 the following figure.

Proof

- If F is satisfiable, let's assume to the contrary: let's assume that there is a literal x_i for which x_i and x̄_i are in the same strongly connected component.
 - By definition, there is path from u to v and v to u, for every vertex u, v

in the strongly connected component \Rightarrow in any truth assignment, the corresponding literals must have the same value (since a path is a chain of implications).

 \Rightarrow all (literals corresponding to) vertices in the same strongly connected component must have the same assignment. This cannot be the case for a literal and its complement. Hence, if a literal and complement are in the same component the formula is not satisfiable, because then $x_i \to \bar{x_i}$ and vice versa, which is a contradiction.

$\forall x_i$, do the following:

- Collapse each strongly connected component into a single vertex.
- This results in a DAG.
- Run topological sort (using DFS) on this DAG.
- If x_i appears in its true from in one component and in its negated form in another, if the component of x_i appears topologically before that of $\bar{x_i}$, then we set x_i to false.
- Alternatively, if the components appear in the opposite order, we set x_i to true.

4

1 . C uses

The truth assignment described above is a satisfying assignment.

Again, let's prove this by contradiction, as above. Suppose it is not a satisfying assignment, i.e., \exists some clause $(x \lor y)$ that is false \Rightarrow both x and y are set to false. This would have happened exactly when the component containing \bar{x} appears after the component containing x (and similarly the component containing \bar{x} appears after the component containing x).

Now, from the clause (x ∨ y), we had the directed edges (x̄ → y) and (ȳ → x) ⇒ the component containing x̄ is before or the same as the component containing y, and the component containing ȳ is before or the same as the component containing x.
But if at the same time the component containing x̄ must be later than the component containing x̄, this would imply that the component containing ȳ must be later than the component containing

$V = 0 - 1 IP \in NPC$

1) $0 - 1 IP \in NP$

We have to show the 'Yes' certificate is polynomial-time verifiable. The certificate (guess) will be the n unknowns $x = [x_1, x_2, \dots, x_n]^T$. To verify the

correctness of such a certificate, we need to verify the inequality $Ax \leq b$, the constraint that the solution must satisfy. But this involves just a matrix multiplication (of an $n \times n$ matrix with $n \times 1$ vector with runtime $\theta(n^2)$) followed verifiable).

2) 0-1 IP is NP-hard

We prove that $3 - SAT \leq_m^p 0 - 1 IP$,

Reduction(F)

- In the 3-SAT, suppose there are n boolean variables x_1, x_2, \ldots, x_n $(x_i \in 0, 1)$ and m clauses in the CNF formula.
- Transform each clause $C_j=(x_i\vee x_j\vee x_k)$ in 3-SAT to a linear constraint $x_i+x_j+x_k\geq 1.$
- If a variable appears negated, as x̄_i, change it to 1−x_i in the corresponding linear constraint.
- To be uniform, change the constraints into standard (≤) form.
- Following the above method, every clause will be changed to to a linear constraint on x.
- There are totally m constraints on n variables x_i.
- Let A be the coefficient matrix of every constraints, and b be the right hand side vector, then A is m × n and b is n × 1 and A.x ≤ b. So the 3-SAT problem is transformed into the 0-1 integer programming problem.
- Since there are m clauses, the transformation can be done in polynomial time O(m).
- 3 − SAT ≤^p_m 0 − 1 IP

 ϕ is satisfiable $\Leftrightarrow \exists$ an n-vector x that solves $Ax \leq b, x \in \{0,1\}^n$

Proof (⇒)

If 3-SAT has a satisfying truth assignment, at least one literal in each clause evaluates to be true. For each literal that evaluates to be true in any given clause, the corresponding term in the corresponding inequality evaluates to 1 (If x_i = 1 in the clause, so it is in the inequality; if x̄_i = 1 in the clause, 1 - x_i = 1 in the inequality).

For each literal that evaluates to be false in any given clause, the corresponding term in the corresponding inequality evaluates to 0 (If
$$x_i = 0$$
 in the clause, so it is in the inequality; if $\hat{x}_i = 0$ in the clause, $1 - x_i = 0$ in the inequality).

• $x_i + x_j + x_k \ge 1$ always holds and so does every inequality constraint.

• Hence, there is an n -vector x of $\{0,1\}^n$, use this value to set the corresponding variables in the clauses.

• Since the inequalities are satisfied, $x_i + x_j + x_k \ge 1$ always holds, there is at least one 3-literal $(x_i \text{ or } 1 - x_i)$ evaluates to 1, and the corresponding x_i or \hat{x}_i evaluates to 1.

• Hence, each clause is satisfied and 3-SAT has a satisfying truth assignment.

Thus, we have proved that F is a polynomial-time reduction and it follows that 0-1-IP is NP-complete.
